

## Arrowsmith Coast WA07.02.03

### Regional Setting

The dominant regional processes are the Mediterranean to arid climate; the El Nino Southern Oscillation (driving sea-level variability); Southern Annular Mode (driving south-westerly swells and storms); strong sea breezes; micro to meso tidal, mainly diurnal; south-westerly swells; southerly seas; and carbonate sediments with moderate northerly longshore transport.

This coastline is susceptible to regional hazards, including extra-tropical cyclones, mid-latitude cyclones (depressions), storm surges, and river flooding (sub-regions only).

This mixed sand and rock coast compartment extends from Illawong to Cliff Head.

### Justification of sensitivity

The sensitivity rating is a 3 as the shoreline is currently stable and likely to remain stable.

The pattern of inshore reefs directly affects coastal dynamics and the formation of local sediment cells. Sediment is derived from on and offshore, especially from biogenic sources, reef erosion and reworking of beach material.

### Other comments

Common landform assemblages:

The coast is mainly rocky, with beaches and dunes over-riding calcarenite pavement reefs, rock platforms, beachrock ramps and lithified eolian sediments. Perched beaches are common. Beachrock dominates beach with occasional sandy sections; may have a low undercut beachrock cliff face (100%).

Geomorphological features include offshore limestone platforms, narrow beaches, limestone cliffs, and dunes.

This compartment has a WNW aspect.

#### **Confidence in sources**

Moderate confidence: Coastal landforms are well described in available management literature. However, neither sediment movement along the rocky coast, and especially through the offshore reef chain, nor the sediment budget for the coast is well known. The inshore extending to the Beagle Islands and into Compartment WA07.02.02 is shallow. Interpretation of landform assemblages comes from satellite imagery and aerial photography, as well as site visits and published information.
